1. Mobiles node aren't supported by Netsukuku algorithms. 1

2.

For the sake of simplicity, in this paper, we will assume to operate on level 0 (the level formed by 256 single nodes).

4 Tracer Packet

A TP (Tracer Packet) is the fundamental concept on which the QSPN is based: it is a packet which stores in its body the IDs of the traversed hops.

4.1 Tracer Packet flood

A TP isn't sent to a specific destination but instead, it is used to flood the network. By saying "the node A sends a TP" we mean that "the node A is starting a TP flood".

A TP flood passes only once through each node of the net: a node which receives a TP will forward it to all its neighbours, except the one from which it

At the end, A will know the route A B C D and F will know the route F E D.

```
current branch can't be explored anymore, therefore it is a
   valid route. Print it */
   print branch
}
```

A proof of concept of the above algorithm has been implemented in Awk [4].

Example

Consider this graph:

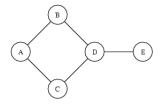

Figure 2: A simple graph with one segment and one cycle

Given this graph as input the algorithm will output:

```
Α
   В
          C
   В
      D
          Ε
Α
   C
Α
      D
         В
   C
Α
      D
         Ε
В
   Α
      C
         D
            Ε
В
   D
      C
          Α
В
   D
      Ε
C
   Α
      В
         D
             Ε
C
   D
      В
         Α
C
   D
      Ε
D
  В
        C
      Α
   C
D
         В
   Ε
```

6 Raw Tracer Packet flood

We can consider each route given by the output of the above algorithm as a

node doesn't forward the RTP to the neighbour from which it has received the packet itself.

Invalid route A route must not be in the form of:

XacaY

where a and c are two nodes. A simplification, which gives a route of this

- 3. In a cycle, just two TP are needed, and one is the reverse of the other. The first can be constructed in this way:
 - Choose a node of the cycle, this will be the pivot node.
 - Start from one neighbour of the pivot and write sequencially all the other nodes until you return to the pivot (but do not include it). Call this string *C*.
 - The TP will be:

CpC

where p is the pivot node.

Example: if we choose the node D as the pivot, we can write the TP as:

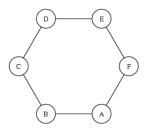

Figure 4: A cycle

EFABCDEFABC

and its reverse:

CBAFEDCBAFE

These two TPs will give all the routes to all the nodes of the cycle.

7.3 The question

Can we implement a "live" version of the Simplify Route algorithm like we did with the Generate Route one? The reply is ahead.

8 Continuous Tracer Packet

A Continuous Trker Plket (CTP) is an extension of the TP flood: a node will

9.1 Interesting information

A node considers a received CTP interesting when its body contains at least a new route, i.e. a route that the node didn't previously know. In other words, if a CTP contains routes already known by the node, it is considered uninteresting.

9.3 Cyclicity

rtt or the bandwidth capacity. If the node has reached the *MaxRoutes* limit, it will substitute the old route with the more e cient one.

Note that this definition is more general than the previous. Indeed, if the node ${\cal S}$ doesn't know the route to reach ${\cal D}$

The underlined routes are the new route for $\it G$. As you can see, in the CTP (10) G doesn't find any new route, so it drops the packet and doesn't

11.2.2 Asymmetry in Q^2

The QSPN v2 is a very flexible algorithm that can be adapted to a large range
